

IN THE ABSTRACT

Please replace the Abstract with the following amended Abstract.

A floating caliper type disc brake is supported by a support member displaceably in an axial direction of a rotor. The disk brake includes pressed-side shim plates respectively lined on reverse surfaces of back plates of pads supported by the support, while supporting-side shim plates are lined on an inner side surface of a claw portion and on a distal end face of a piston. The pressed-side shim plates and the pressing-side shim plates are respectively retained by mating members. One surface of each of the mutually opposing pressed-side shim plates and one surface of each of the pressing-side shim plates are slidably abutted against each other.
